HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

OPEN ACCESS

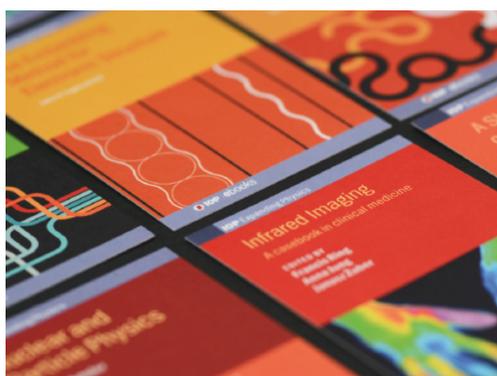

Excitation energy distributions and statistical dissociation of C_{70}^{2+} prepared in collisions with F^+ ions at 3 keV

Synopsis The statistical dissociation of C_{70}^{2+} has been studied as a function of the internal energy using collision induced dissociation under energy control (CIDEC). Doubly charged ions C_{70}^{2+} were prepared in F^+ (3 keV) + $C_{70} \rightarrow F^+ + C_{70}^{2+}$ collisions. Up to seven successive evaporation of C_2 have been observed in a time range of 1.7 μ s. The dissociation energies of C_{70-2m}^{2+} ($m=1-7$) were determined using a statistical cascade model to reproduce the excitation energy distribution of C_{70}^{2+} parent ions for each dissociation channel. Results are in good agreement with previous theoretical calculations.

The fragmentation pattern of C_{70}^{2+} is studied with well-controlled internal excitation energy in $F^+ + C_{70} \rightarrow F^+ + C_{70}^{2+}$ collisions using the CIDEC method [1]. By analyzing the kinetic energy loss of the scattered negative ions F^- , the internal energy distribution of the doubly charged C_{70} parent ions has been obtained for the main dissociation channels, i.e., the successive evaporation of C_2 units.

As expected, the dissociation of C_{70}^{2+} presents a statistical behavior. Indeed, for the first C_2 emission the average excitation energy of the C_{70}^{2+} parent ion is about 53 eV which is much larger than the dissociation energy (9.5 eV). For the second and third evaporations, an extra amount of energy of about 8 and 16 eV is required, respectively. In the time range of the experiment (1.7 μ s) up to seven C_2 evaporation have been observed leading to C_{56}^{2+} daughter ion (figure 1). The corresponding internal energy of the C_{70}^{2+} parent ion is about 100 eV. It is noteworthy that the C_{60}^{2+} daughter ion appears at excitation energy of about 81 eV. An extra 8.5 eV leads to the formation of C_{58}^{2+} fragment. From previous experiment [1] the internal energy of the C_{60}^{2+} parent ions was measured to be about 45 eV for the emission of the first C_2 unit. This tends to indicate that C_{60}^{2+} ions formed from C_{70}^{2+} parent ion may have a rather high excitation energy.

Using the Arrhenius law to calculate the dissociation rates, the internal energy distributions were reproduced with a cascade statistical model without any assumption on the excitation energy. The obtained dissociation energy of C_{70-2m}^{2+} ($m=1-7$), treated as free

parameters in the model, are found in good agreement with previous calculations [2].

The ionization process of C_{70}^{2+} in competition with the C_2 evaporation channel will also be discussed.

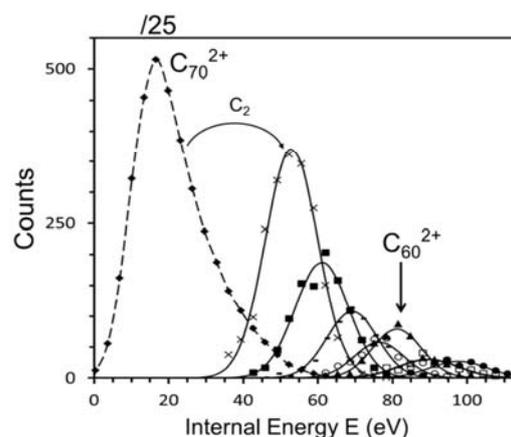

Figure 1. Symbols: experimental internal energy distributions of C_{70}^{2+} parent ions for successive C_2 evaporations. The amplitude of the C_{70}^{2+} peak has been divided by a factor 25 and the dash line is to guide the eyes. Plain lines: Gaussian fits of the energy distributions of C_{70}^{2+} parent ions leading to C_{70-2m}^{2+} ($m=1-7$) daughter ions.
